

**Amendments to the Claims:**

This listing of claims will replace all prior versions, and listings, of claims in the application:

**Listing of Claims:**

1. (Currently Amended) Mask (MM) having patterns (MF), for a lithography device operating by reflection of a beam of photons of a wavelength less than about 120 nm, comprising a planar substrate (ST) connected to a reflective structure ([SIR]SMR) comprising a front face equipped with selected patterns (MF), formed from a material absorbent to the said wavelength, characterised in that it comprises protective means (SP) contacting the reflective structure ([SIR]SMR) and transparent to the said wavelength and contrived to keep interfering particles (PP) at a distance (H) from the patterns (MF) which is greater than or equal to one of two values taken from a depth of focus (doF) of the device and a height of pattern/interfering particle (h) associated with a tolerated percentage of absorption of photons by the interfering particles (PP) which is a function of their diameter (d), and characterised in that the protective means (SP) form a structure having a membrane (ME) connected by pillars (PS) to the front face of the reflective structure, and in a position substantially parallel to the front face, the thickness of the membrane (ME) and the height of the pillars (PS) being such that their sum is equal to the selected distance (H), the pillars (PS) contacting at least one of the patterns (MF).

2. (Original) Mask according to claim 1, characterised in that the protective means (SP) are contrived to keep the interfering particles (PP) at a distance (H) from the patterns (MF) which is greater than or equal to the two values taken by the depth of focus (doF) of the device and the height of pattern/interfering particle (h).

3. (Original) Mask according to either of claims 1 or 2, characterised in that the protective means (SP) form a structure having a maximum variation of optical thickness selected so as to

bring about locally a deflection of the beam which is negligible compared to the precision of placing of the patterns (MF).

4. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a structure which brings about substantially no phase variation between photons of the beam reflected by the mask.

5. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a hydrophobic structure.

6. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a structure of which at least a front face, opposite to the patterns (MF), is capable of being cleaned of some at least of the interfering particles (PP) which it holds.

7. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a structure capable of being inspected, with a selected contrast, by means of observation means operating in the visible or ultraviolet range.

8. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a conductive structure capable of thermophoresis.

9. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a conductive structure capable of applying an electrostatic effect.

**Appln No. 10/587,194**  
**Amdt date February 3, 2010**  
**Reply to Office action of August 3, 2009**

10. (Original) Mask according to claim 9, characterised in that the electrostatic effect is intended to repel the interfering particles (PP).

11. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a structure which is non-diffracting and non-diffusing in the ultraviolet range.

12. (Previously Presented) Mask according to claim 1, characterised in that the distance (H) is between about 50 nm and about 5000 nm.

13. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a structure placed on the front face of the reflective structure and parallel thereto, and comprising at least one antireflective layer.

14. (Previously Presented) Mask according to claim 1, characterised in that the protective means (SP) form a structure composed of a foam.

15. (Currently Amended) Mask (MM) having patterns (MF), for a lithography device operating by reflection of a beam of photons of a wavelength less than about 120 nm, comprising a planar substrate (ST) connected to a reflective structure (SMR) comprising a front face equipped with selected patterns (MF), formed from a material absorbent to the said wavelength, characterised in that it comprises protective means (SP) contacting the reflective structure (SMR) and transparent to the said wavelength and contrived to keep interfering particles (PP) at a distance (H) from the patterns (MF) which is greater than or equal to one of two values taken from a depth of focus (doF) of the device and a height of pattern/interfering particle (h)

Reply to Office action of August 3, 2009

associated with a tolerated percentage of absorption of photons by the interfering particles (PP) which is a function of their diameter (d), and Mask according to claim 1, characterised in that the protective means (SP) form a structure formed from a material, placed on the front face of the reflective structure ([SIR]SMR) and defining channels (CX) making it possible to reduce the density of the material, at least one of the patterns (MF) being accessible to the channels.

16. (Canceled)

17. (Currently Amended) Mask (MM) having patterns (MF), for a lithography device operating by reflection of a beam of photons of a wavelength less than about 120 nm, comprising a planar substrate (ST) connected to a reflective structure (SMR) comprising a front face equipped with selected patterns (MF), formed from a material absorbent to the said wavelength, characterised in that it comprises protective means (SP) contacting the reflective structure (SMR) and transparent to the said wavelength and contrived to keep interfering particles (PP) at a distance (H) from the patterns (MF) which is greater than or equal to one of two values taken from a depth of focus (doF) of the device and a height of pattern/interfering particle (h) associated with a tolerated percentage of absorption of photons by the interfering particles (PP) which is a function of their diameter (d), and Mask according to claim 1, characterised in that the protective means (PS) form a structure composed of nanotubes oriented in-to extend along a selected direction relative to the substantially normal (N) to the front face of the reflective structure ([SIR]SMR), the nanotubes contacting at least one of the patterns (MF).

18. (Previously Presented) Mask according to claim 13, characterised in that the at least one antireflective layer is composed of a material selected from at least polymers transparent to the said wavelength, carbon, carbon nanotubes, silicon, beryllium, ruthenium, silver or zirconium.

19. (Canceled)
